Introduction

Result

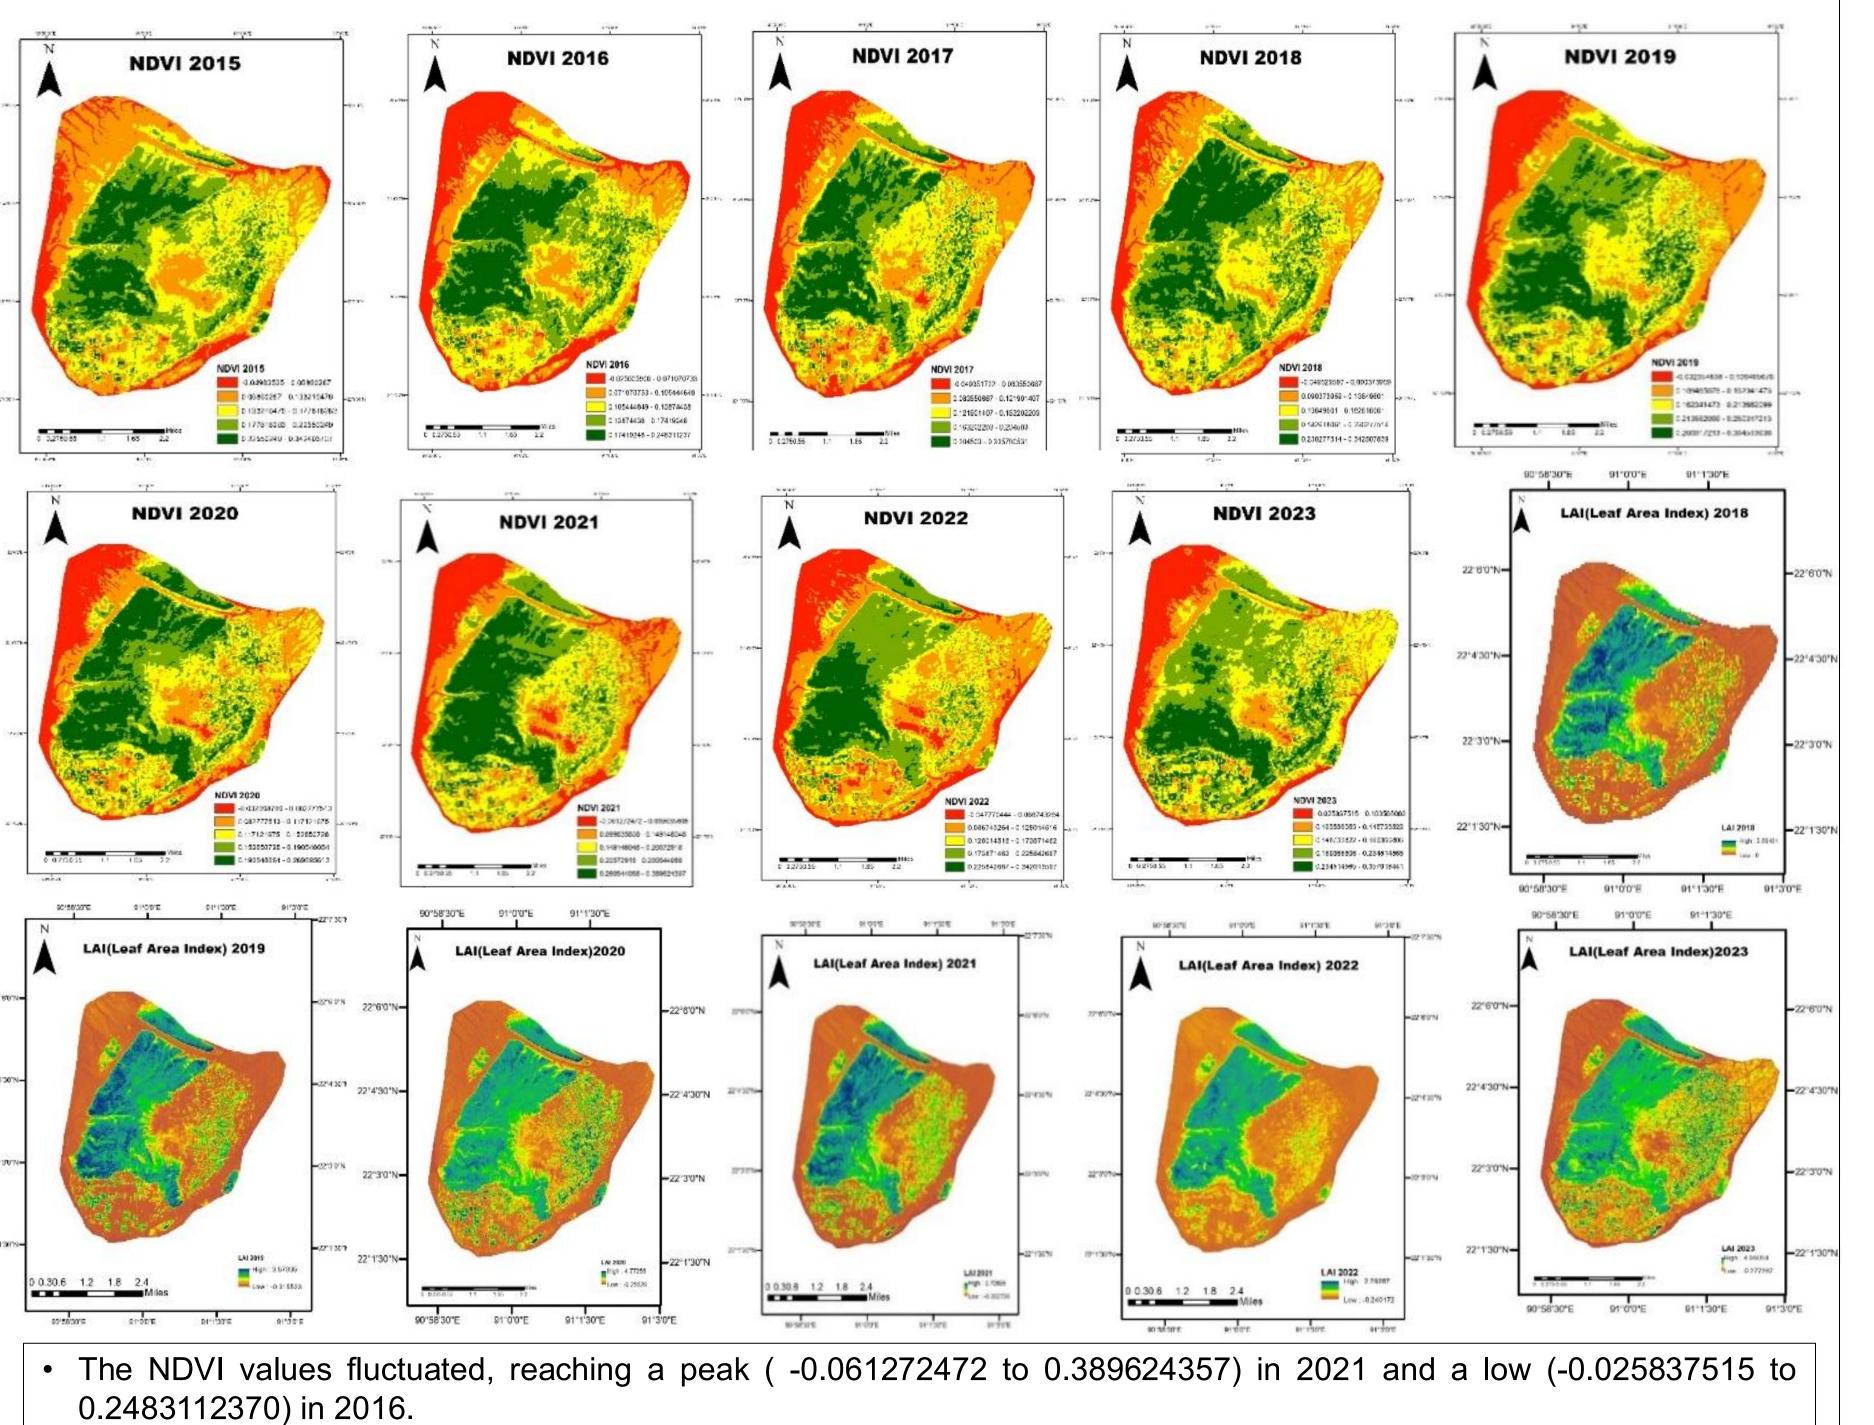

Forest biomass is the total weight of living organisms in a specific area at a given time in a forest.

- NDVI approximates the health of plants by noting how much near-infrared and red light they reflect. Healthy vegetation absorbs more red light for photosynthesis and reflects more near-infrared light.
- Leaf Area Index (LAI) estimation measures how much of an area leaves cover. It provides insights into vegetation density and growth.
- Land Use and Land Cover (LULC) estimation looks at what kind of land use and how they change over time. It is essential for environmental monitoring, urban planning, and resource management.

Objectives

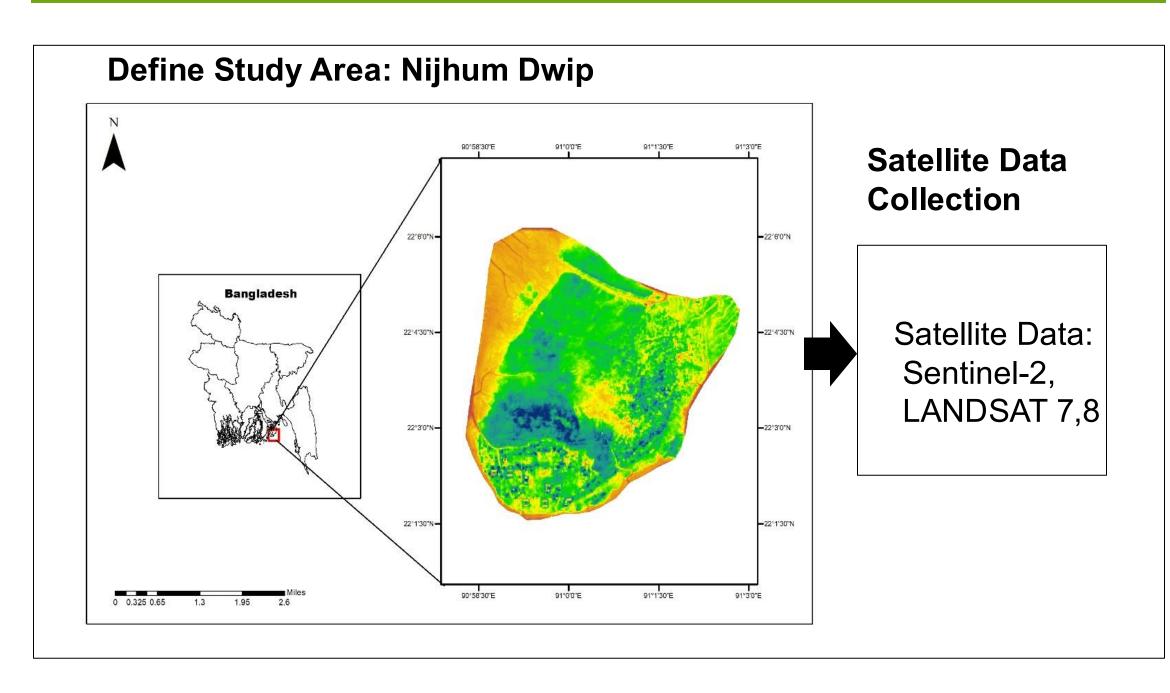

Investigating the Normalized Difference Vegetation Index (NDVI)

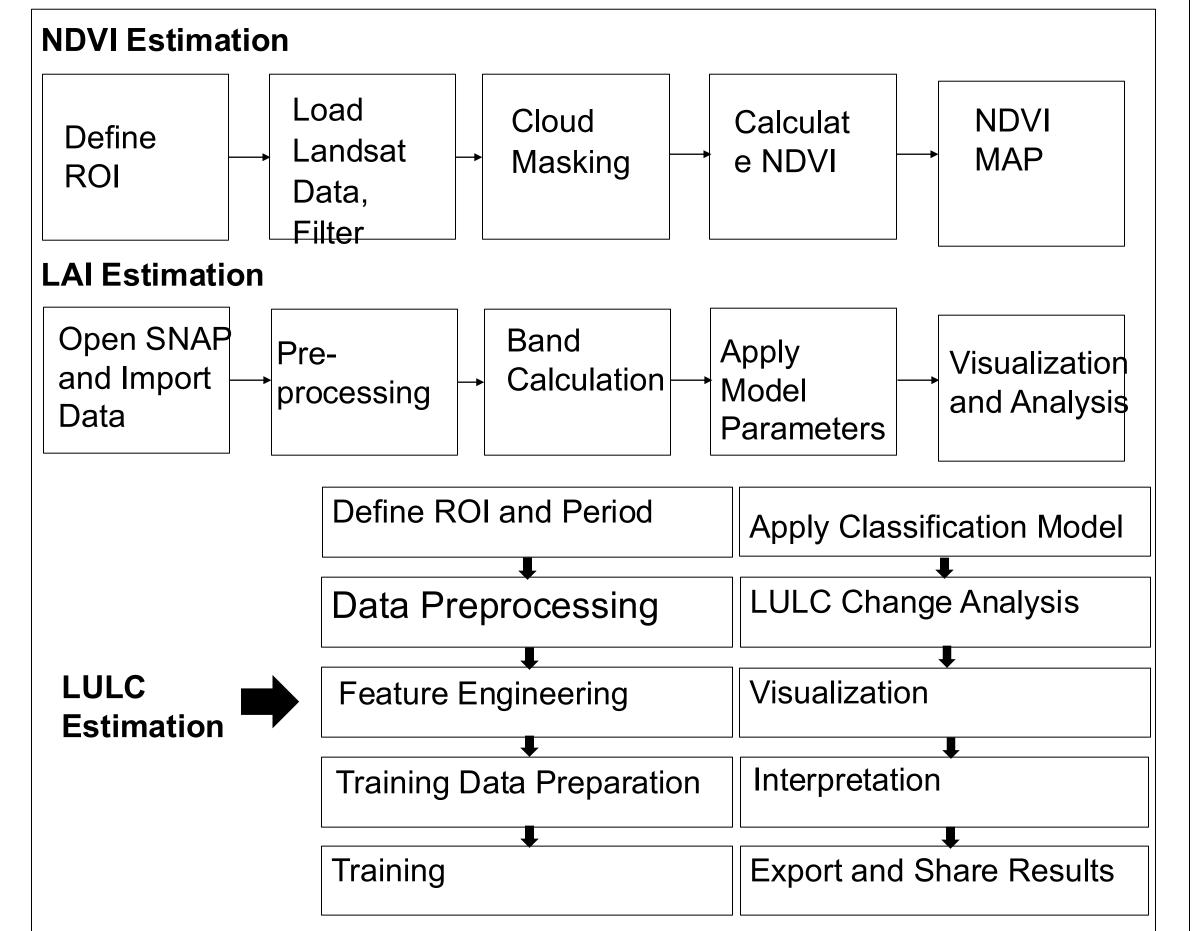

Investigating the Leaf Area Index (LAI)

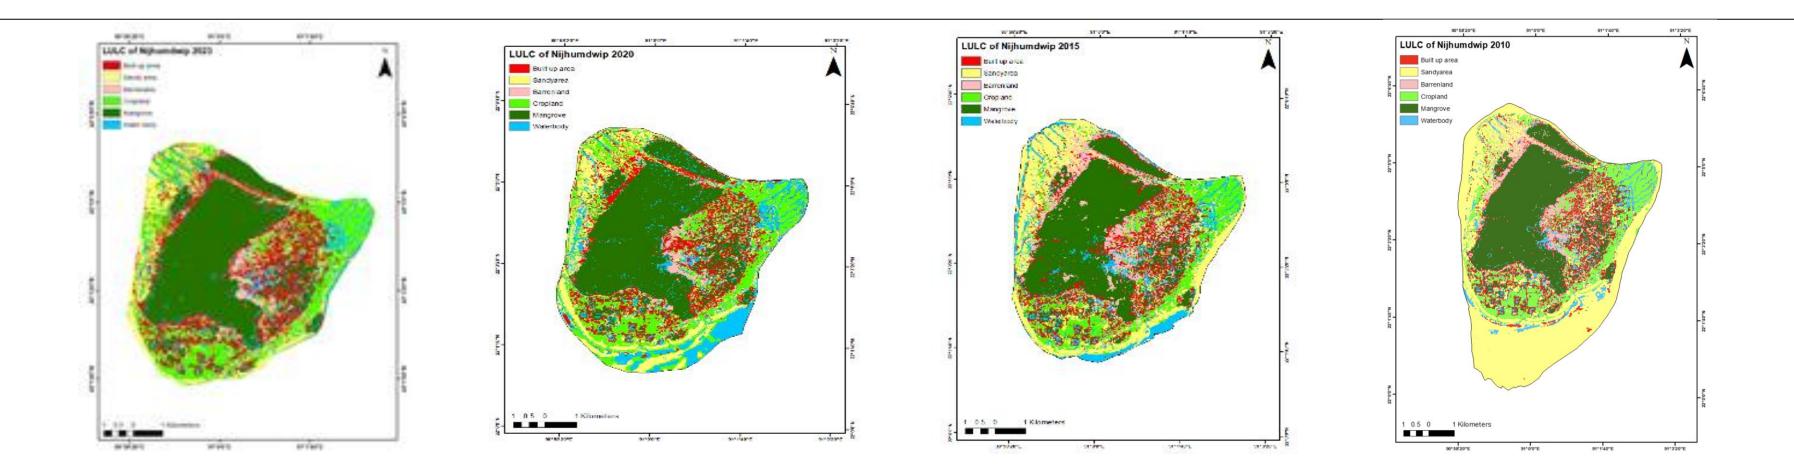

- Investigating the Land Use and Land Cover (LULC)
- Investigating the relation between NDVI and LAI
- Investigating the relation between NDVI and LULC

Methodology

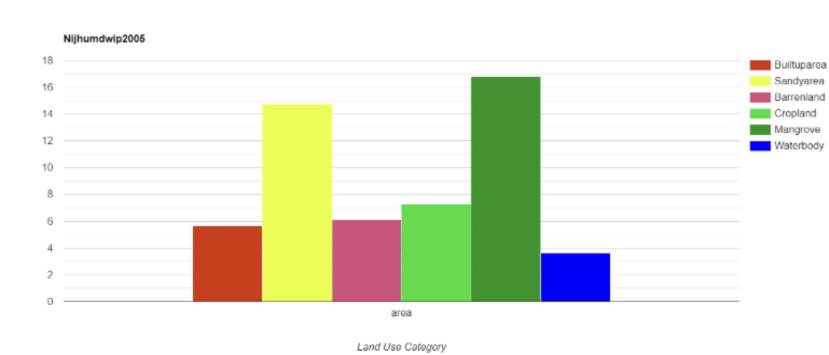

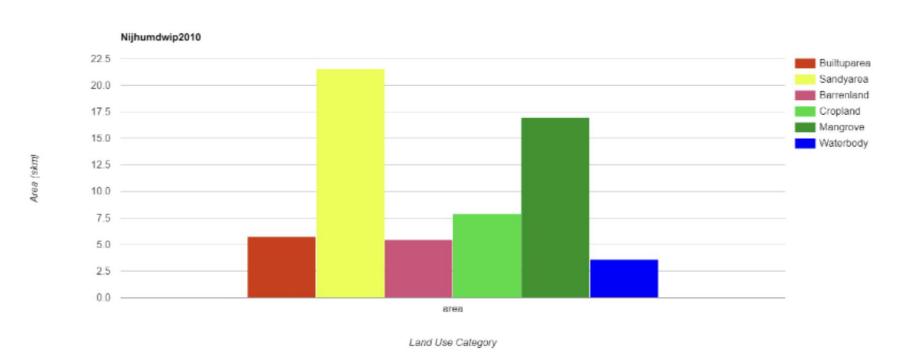

The LAI value was the highest in 2023 ranging from 4. 96058 to -0.277276 and the lowest LAI value was in 2018 ranging from 2.60431 to 0

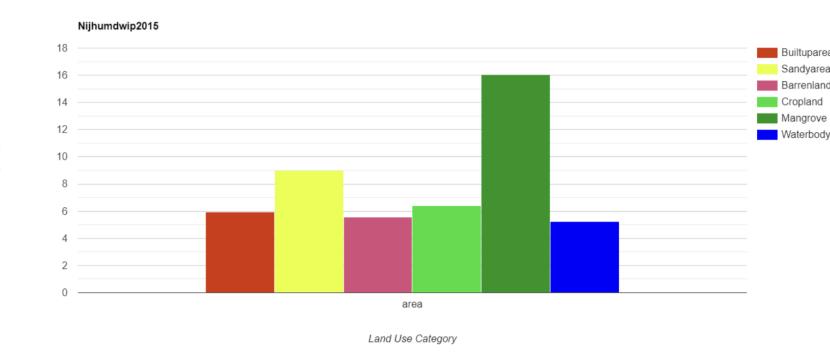

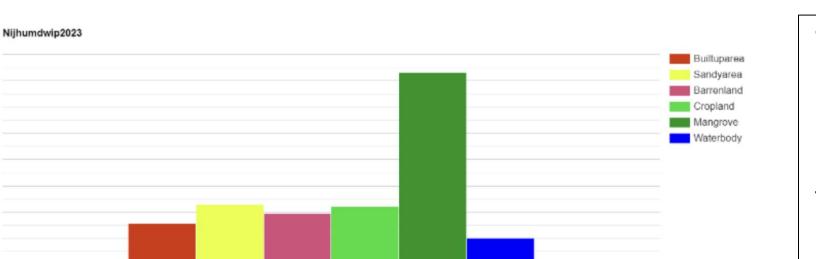

Key Findings

- Rising NDVI and LAI indicate increasing vegetation cover and biomass.
- Need for continued monitoring of LULC changes, particularly mangrove cover.

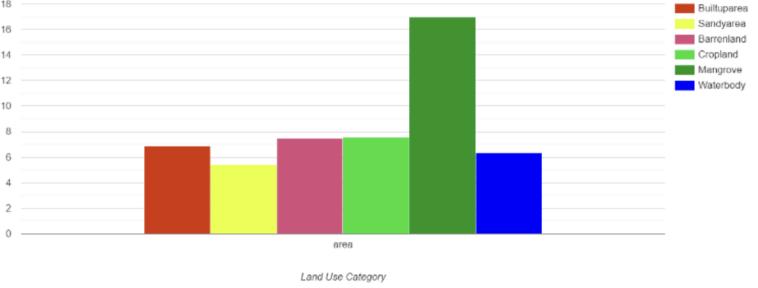

The built-up area expanded from 10.40% in 2005 to 11.5% in 2023, indicating urbanization trends. Sandy areas increased from 27.25% in 2005 to 35.24% in 2010 but declined thereafter. Barren land fluctuated, decreasing from 11.29% in 2005 to 8.90% in 2010, then rising to 14.63% by 2023. Cropland exhibited a general upward

trend, except in 2010. Mangrove coverage, starting at 30.98% in 2005, fluctuated, reaching 37.16% in 2023.

Nijhumdw

Conclusion

This study highlights the interactive dynamic between human activities and natural processes. Dynamic NDVI value fluctuation can indicate alterations in the health and density of vegetation over the years due to climate change, over exploitation or reclamation of land. Similarly, the LAI values indicate a positive upward trend, which represents an improved quality of vegetation cover and health during this period this is likely due to reforestation. The changes in LULC highlight the large percentage of mangrove area in comparison to land exhibiting people consciousness towards protecting forest biomass.
